Background

There are a number of vector hazards to consider in West Africa. Mosquito, Sand Fly and Tick-borne diseases are prevalent throughout the year. The vectors of malaria, dengue fever, chikungunya virus, yellow fever, West Nile virus, Rift Valley fever, Japanese encephalitis, Leishmaniasis and Crimean-Congo hemorrhagic fever occur in this area. The purpose of this brief is to help those traveling to and living within West Africa to learn more about their risk of vector-borne disease infection. All maps are available for download on VectorMap.org. More information on mosquito and sand fly vectors can be found at WRBUorg.

Monthly Climate Maps

Click here to view the maps described below

Rainfall
This map shows the accumulated rainfall for the past month. Updated monthly.
-NASA Earth Observations

Consistent Above and Below Average Precipitation
Areas with consistent above average monthly rainfall over the past 3 months may indicate increased mosquito breeding sites which may lead to increased mosquito-borne disease transmission. Areas with consistent below average rainfall may also indicate increased water storage or ponding which can provide additional habitat for mosquito species that lay eggs in human containers, protected micro environments, or long lasting pools. Updated monthly. -NASA Earth Observations.

Drought Breaking Rain
Areas receiving above average rainfall for the past month and below average rainfall for the previous 12 months. Drought breaking rain may indicate recent suitable conditions for vectors and diseases in a stressed environment or human population. Updated monthly. -WorldClim, Giovanni online data system NASA GES DISC, Tropical Rainfall Measuring Mission (TRMM).

Temperature anomaly
This map shows where earth’s temperatures were warmer or cooler in the daytime for the past month than the average temperatures for the same month from 2001-2010. Updated monthly.
-NASA Earth Observations

Land Surface Temperature
This map shows the temperature of the earth’s lands during the daytime. Updated monthly.

Malaria

Malaria is a mosquito borne disease caused by parasites of the genus Plasmodium. It is primarily spread through the bite of mosquitoes of the genus Anopheles. Symptoms of malaria are flu-like including high fever and chills. According to the CDC there were an estimate 219 million cases of malaria world-wide in 2010 with approximately 91% of infections occurring in Africa (CDC, 2014).
Malaria
(Plasmodium falciparum)

Temperature Suitability Index for *P. falciparum*
Gething et al. 2011

Number of months per year where mean temperatures can support infectious mosquito populations.
Gething, et al. 2011

Estimated proportion of children aged 2-10 years that are infected with *P. falciparum*. Averaged out over 12 months of 2010. Malaria Atlas Project

Habitat suitability model:
Anopheles gambiae s.l.
Habitat suitability model: *Anopheles arabiensis*
Habitat suitability model:
*Anopheles wellcomei*
Habitat suitability model: *Anopheles funestus*
Habitat suitability model: *Anopheles nili*
**Anopheles (Cel.) gambiae Giles, 1902**

**Bionomics:**
This species occurs in a great variety of types of water; the most striking are the shallow, open sun-lit pools. Females readily enter houses and bite man both indoors and outdoors starting at sunset and peaking just at dawn (Gillies and deMeillon 1968).

**Medical Importance:**
Primary malaria vector (Gillies and deMeillon 1968).

*Note: An. gambiae and An. arabiensis are morphologically identical and can only be differentiated using molecular techniques.*
**Bionomics:**
*An. arabiensis* larvae are found in relative short duration habitats (3-5 weeks) with high turbidity and lacking in aquatic vegetation or surface film. Chosen breeding sites appear to be associated with cattle, the preferred host. (Gimnig, Ombok, Kamau and Hawley 2001:286)

**Medical Importance:**
Primary malaria vector (Gillies and deMeillon 1968).

**Note:**
*An. gambiae* and *An. arabiensis* are morphologically identical and can only be differentiated using molecular techniques.
Anopheles (Cel.) wellcomei Theobald, 1904

**Bionomics:**
Larvae are found in swamps with vertical and horizontal vegetation, streams with grassy margins, rice fields and vegetation along large rivers even in areas of high forest. Females will enter houses to bite but are mainly zoophilic. Biting activity begins at dusk and peaks at about 2300, after which it gradually decreases (Gillies and deMeillon 1968).

**Medical Importance:**
Possible malaria vector (Gillies and deMeillon 1968).
Anopheles (Cel.) funestus Giles, 1900

Bionomics:
In most parts of its range, An. funestus breeds characteristically in bodies of clear water that are either large and more or less permanent, e.g. swamps (near edges if deep), weedy sides of streams, rivers, furrows or ditches, protected portions of lake shore, ponds, etc., especially when weedy, or water such as seepages, which are fed from underground permanent sources (Evans 1938). A. funestus is one of the most anthropophilic mosquitoes known. The great bulk of feeding takes place inside houses after 2200 up to dawn (Gillies and deMeillon 1968).

Medical Importance:
Vector of malaria and bancroftian filariasis (Gillies and deMeillon 1968).

WRBU Catalog Species Page
Anopheles (Cel.) nili (Theobald, 1904)

Bionomics:
Principally a stream breeder, larvae being found in vegetation or in dense shade along the edges of streams and large rivers. Symes (1931a) found that out of 163 collections of larvae of this species in Kenya, 139 were taken from streams. Variable in behaviour in both feeding and resting habits. In Liberia, Barber et al. (1932), Sierra Leone, Gordon et al. (1932) Upper Volta, Hamon, Choumara et al. (1959), Dahomey, Hamon, Rickenbach and Robert (1956) Nigeria, Service (1963a), Cameroun, Hamon and Mouchet (1961), Chad, Lacan (1958), and in parts of the Sudan, Lewis (1956a), it is an anthropophilic species biting man readily indoors and outdoors and frequently resting indoors by day. It has also been recorded as quite common in houses in the West Nile district of Uganda, Kafuko et al. (1962). (Gilies and deMeillon 1968:85)

Medical Importance:
An important malaria vector in many parts of West Africa. Wherever man-biting occurs infected specimens are found. (Gilies and deMeillon 1968:85)

Dengue Fever and Chikungunyaa virus

According to the CDC, dengue fever is the leading cause of illness in the tropics and subtropics. Dengue fever is caused by a group of viruses. Symptoms of Dengue include high fever, severe headache and joint pain (CDC, 2014).

Chikungunya (pronounced: ‘chik-en-gun-ye’) virus (CHIKV) is transmitted to humans by mosquitoes of the genus Aedes. The most common symptoms of chikungunya virus infection are fever and joint pain. Other symptoms may include headache, muscle pain, joint swelling, or rash (CDC, 2014).

Currently, there is no vaccine to prevent or medicine to treat dengue and chikungunya viruses.
Countries reporting CHIKV cases to CDC as of March 2015
Habitat suitability model: 
*Aedes aegypti*
Primary Vectors of CHIKV

*Aedes (Stg.) aegypti* (Linnaeus, 1762)
“Yellow Fever Mosquito”

**Bionomics:**
In association with man, *Ae. aegypti* will use any and all natural and artificial containers. Away from urban areas the species tends to favor pools in river beds, tree stumps, tree holes and natural containers. Females are primarily day biters and readily enter buildings to feed. They have also been taken in lesser numbers at night (Christophers 1960).

**Medical Importance:**
This species is a primary vector of dengue, chikungunya virus and yellow fever (Christophers 1960).

[WRBU Catalog species page](#)
Yellow Fever

Yellow fever is a mosquito borne disease caused by an RNA virus of the genus Flavivirus. It is spread by mosquitoes feeding on infected human or non-human primates. In West Africa, the yellow fever virus is primarily spread by mosquitoes of the genus Aedes. A yellow fever vaccine has been developed and is recommended for anyone traveling to areas where the disease is commonly transmitted. (CDC, 2014).
Predicted Probability of Occurrence of Yellow Fever

- University of Oxford, 2006

Countries Reporting Yellow Fever
-CDC, 2010
Rift Valley fever is a mosquito borne illness caused by a virus of the genus Phlebovirus and is most commonly found in livestock but can also be transmitted to humans. Symptoms of RVF include mild illness, general pain and dizziness. RVF is most commonly found in Africa, however outbreaks have occurred in the middle East as well (CDC, 2014).
Rift Valley Fever Virus: Endemic Areas

-DoD-GEIS
Habitat suitability model: *Culex pipiens*
Habitat suitability model: 
*Culex antennatus*
**Bionomics:**
Larvae are found in numerous and variable breeding places ranging from highly polluted cesspits to clear water pools and containers. This species usually breeds in stagnant water in either shaded or unshaded situations. Females readily attack man both indoors and outdoors (Harbach 1988).

**Medical Importance:**
It has been found naturally infected with Sindbis virus and West Nile viruses in Israel, West Nile and Rift Valley Fever in Egypt, and is a primary vector of periodic Bancroftian filariasis (Harbach 1988).

[WRBU Catalog Species Page]
**Culex (Cux.) antennatus (Becker, 1902)**

**Bionomics:**
Larvae are commonly found in stagnant fresh ground water habitats that include rice fields, stream pools, springs, ponds, swamps, ditches, seepages and animal footprints. Females are evening biters, feeding primarily on cattle, but entering houses to bite man (Harbach 1988).

**Medical Importance:**
Vector of West Nile virus and Rift Valley Fever (Harbach 1988).
